Abstract The purpose of this paper is to identify and analyze Nordic doctoral dissertations in logistics and supply chain management (SCM) published from the years 2009–2014. The paper is based on a detailed review of 150 doctoral dissertations. Compared with previous studies, this paper identifies a trend toward: more dissertations based on a collection of articles than monographs; more dissertations focusing on inter-organizational SCM issues; a shift from a focal company perspective to functional aspects and supply chain-related research; and finally, a continued decreased focus on the philosophy of science. A score for measuring the significance of article-based dissertations is also proposed.

Keywords Doctoral dissertations · Collection of articles · Monographs · Dissertation score · Logistics and supply chain management

1 Introduction

One way to keep track of the progress of logistics and supply chain management (SCM) discipline is to analyze the doctoral dissertations within the research area. By

reviewing such dissertations, it will be possible to gain some interesting information regarding the development and direction of research within the discipline. Specifically, such a review will help us to understand the different approaches in relation to research framework, methodologies, theories applied and the empirical interpretations. Furthermore, the review could not only provide valuable insights into potential research gaps within the discipline, but also pave way for recognizing interesting topics for future research [13, 41]. Besides, given that PhD students are likely to form the next generation of established researchers, research conducted by them is important to the SCM discipline as it helps keeping the discipline on track with emerging topics as well as stimulate theory generation.

The number of PhD students in the Nordic countries has increased significantly during the last decades [24, 41]. Based on the rise in the number of dissertations as well as their varying content, it is interesting to investigate the requirements that are part of completing a PhD dissertation. There has been an escalation in dissertations that are based on collections of articles instead of a monograph [41]. A reason for this might be an increasing pressure to publish at the universities [21], which might be driving PhD students to learn and master the craft of publishing from the very start of their career. No matter what, the culture of many research departments is characterized by a high focus on performance in terms of publications in ranked journals [2, 20, 22, 27]. Therefore, by choosing an article-based dissertation, PhD students might have a better opportunity to work together with other PhD students and senior researchers; in doing so, they also learn how to “play the game.”

The first two comprehensive digest of doctoral dissertations completed within the Nordic countries was

conducted by Gubi et al. [13] and Zachariassen and Arlbjørn [41]. These efforts provide PhD students, other academic staff as well as practitioners with an overview of what has been researched within the logistics and SCM area. These studies have also facilitated the comparison of Nordic dissertations themes to those in the USA (e.g., compiled by Stock [31] and Nakhata et al. [25]). Prior research has demonstrated that much confusion exists concerning SCM definitions and its overlap with logistics [32]. This paper extends the work of Zachariassen and Arlbjørn [41] that applies what Halldórsson et al. [14] call a relabeling approach between the terms of logistics and SCM. The purpose of this paper is to document the progress of doctoral work in logistics and SCM within the Nordic countries between 2009 and 2014. In all, 120 relevant dissertations were identified; however, we were unable to retrieve eight dissertations either in physical form or electronically; therefore, only 112 dissertations were reviewed. With a point of departure within the dimensions and classified categories of these two above-mentioned reviews, this paper provides two analyses:

1. An analysis of identified Nordic dissertations from the year 2009–2014; and
2. A longitudinal analysis that compares the above analysis with the result from Gubi et al. [13] and Zachariassen and Arlbjørn [41].

Accordingly, the analyses within this paper will not only reveal several important insights, but also identify new, potential research areas within the logistics and SCM discipline. Based on these insights, it will be possible to coordinate future research efforts and avoid any unnecessary replication or duplication of previous work.

The rest of the paper is organized as follows: Sect. 2 provides a brief literature review of earlier contributions dealing with doctoral dissertation reviews. Section 3 discusses the methodology used in this study; it also outlines the limitations concerning the chosen methodology. Subsequently, Sect. 4 discusses the results obtained from analyzing the Nordic dissertations. Finally, Sect. 5 concludes with the overall purpose of the paper and some directions for future research activities.

2 Extant literature on doctoral dissertations in logistics and supply chain management

Several authors have analyzed and classified doctoral dissertations in logistics and SCM, both within the Nordic countries as well as the USA. In this section, nine prior studies—seven American studies and two Nordic studies—are briefly mentioned so as to identify the trends in topical coverage through the years and to see whether there are any

similarities between the topics chosen by PhD students across the Atlantic.

The first study of compendiums of PhD research in logistics conducted by Stock back in 1987 [28] examined 684 dissertations from the period 1970–1986 [29]. Subsequent reviews were conducted in (1) 1993 covering 422 American dissertations that were completed in the period of 1987–1991 [34] and (2) 2001 with an analysis of 317 PhD dissertations completed in the period of 1992–1998 [31]. In 2006, Stock completed his fourth review of PhD dissertations together with Broadus [33]. This study showed a distinct increasing trend in the number of dissertations within SCM- and/or logistic-related areas in the period from 1999 to 2004 when compared to the period covered by the 2001 study. But surprisingly, the count between 1999 and 2004 fell short of the overall levels of 1987–1991. A more interesting finding of the 2006 study was that the dissertations were more multifaceted due to the fact that they closely mirrored the cross-functional and boundary spanning nature of logistics; at the same time, their multifaceted nature made the classification task more difficult.

Another American study was conducted by Das and Handfield [8] wherein the authors investigated 117 PhD dissertations from the period 1987–1995 in order to evaluate the intellectual health of the purchasing discipline. The study was an extension of a previous research on purchasing dissertations conducted by Williams [39] to identify the key focus areas of research in the prior decade. In this study, Williams concluded that the key focus areas covered were supplier selection and development, information systems, organizational and measurement issues, negotiation and purchasing ethics.

The most recent review covering US dissertations was conducted by Nakhata et al. [25]. In this study, the authors reviewed 609 doctoral dissertations completed between 2005 and 2009. The number of identified dissertations in this study is significantly larger than the four reviews conducted by Stock and colleagues and clearly reflects a significant increase in colleges/universities graduating doctoral students within logistics- and supply chain-related areas. Nakhata et al. [25] also point out that a forthcoming retirement of academic “baby boomers” during the period 2005–2020 may explain the increase in the PhD production. The most prominent research methodologies employed by doctoral students in the study of Nakhata et al. [25] are modeling, simulation and empirical quantitative methods.

Two earlier studies of Nordic doctoral dissertations within logistics and SCM have been disseminated in academic journals. The first was developed by Gubi et al. [13], who reviewed 71 Nordic dissertations published between 1990 and 2001. Most of the dissertations were published as monographs with manufactures and carriers as the primary

entity of analysis. The most recent Nordic contribution is by Zachariassen and Arlbjørn [41] wherein the authors analyze the development in Nordic doctoral research in logistics and SCM from the years 2002–2008. As opposed to Gubi et al. [13], Zachariassen and Arlbjørn [41] found more dissertations based on a collection of articles, which was reflective of a response to increase publication pressure. In contrast to the Gubi et al.'s [13] study, the primarily entity of analysis of most dissertations was the manufacturing companies. While prior reviews showed a focal company perspective, the review of Zachariassen and Arlbjørn [41] documented a shift toward an inter-organizational perspective covering dyadic and supply chain units of analysis. Additionally, according to Zachariassen and Arlbjørn [41], there has also been a decreased focus on the philosophy of science, since most dissertations were being published as collections of articles.

3 Method

The method applied for identifying, collecting and reviewing the doctoral dissertations in this paper follows a three-step process. These steps are explained in the following subsections.

3.1 Identifying and collecting Nordic doctoral dissertations

The first step consisted of sending e-mails to contact persons at different research institutions within the Nordic countries (i.e., Denmark, Finland, Iceland, Norway and Sweden) as outlined in [41]. Based on this e-mail contact, the list was further modified (e.g., adding University of Vaasa in Finland and Linnaeus University and Örebro University School of Business in Sweden). The final list included 39 research institutions which are presented in "Appendix 1." A contact person at each of the 39 research institution was identified and was contacted by e-mail. The e-mail provided a clear statement of the research project and requested the list of completed doctoral dissertations within logistics and SCM within the analysis period. This process provided an initial list of 120 dissertations. Majority of these dissertations were accessible in electronic form (we either received them by e-mail or downloaded them from the corresponding institution's Web site). The rest of the dissertations were available in hard copy form.

3.2 Validating the initial list of doctoral dissertations

The second step was concerned with the validation of the identified dissertations by senior researchers from each of

the Nordic countries. This step was completed by e-mailing the initial list to these senior researchers and by attending the 27th annual NOFOMA conference in June 2015 at Molde University College. This process resulted in the inclusion of an additional 41 dissertations, thereby increasing the total count to 161.

3.3 Reviewing the received dissertations

In the third step, a detailed review of the 161 dissertations took place. During this process, three dissertations were excluded since they were judged as not being within the scope of the present analysis. Out of this net list of 158, it was possible to conduct reviews of 150 dissertations. As mentioned earlier, we were unable to retrieve eight dissertations as well as there was no response from the authors when we e-mailed them requesting for the copy of their dissertation. A complete list of the dissertations is included in "Appendix 2." The detailed review took place against a review framework as described in [13, 41]. Our analysis covered additional review elements as the dissertations were mostly based on a collection of articles. These elements were: (1) number of articles, (2) type of article (journal publication, book chapter, conference paper, working paper or unpublished paper), (3) year of publication, (4) ranking of the journal, (5) number of authors on each article and (6) the doctoral candidate's author number for the specific article.

3.4 Limitations

This dissertation review has some limitations that are worthwhile to mention. First, even though the gross list of dissertations was reviewed and validated by senior researchers within the Nordic countries, there is a possibility that some dissertations were not identified. Second, reviewer subjectivity could not be completely eliminated in the review of the 150 dissertations. However, in order to minimize subjectivity, an aligned interpretation of the review elements and their outcome was obtained by a common review of three different types of dissertations (one monograph and two article-based dissertations). Third, the list of dissertations that was composed and reviewed stems from the NOFOMA research community. Obviously, other Nordic researchers may produce doctoral dissertations that deal with topics under the scope of this review, but is outside the NOFOMA radar (e.g., researchers belonging to European Decision Sciences Institute (EDSI), European Logistics Association (ELA), European Operations Management (EurOMA), International Purchasing and Supply Education and Research Association (IPSERA) or Logistics Research Network (LRN) or Rencontres Internationales de Recherche en Logistique (RIRL)

(International Research Conference on Logistics and Supply Chain Management). This study can make observations only based on the dissertations reviewed under the NOFOMA umbrella. Fourth, since the contact persons were not provided with a definition of logistics and SCM, they might have excluded some dissertation that could have fallen within the scope of this analysis. Moreover, the senior researchers whom we e-mailed for dissertations might not be from the department of logistics and SCM. Therefore, including definitions for logistics and SCM will have no impact.

4 Analysis

This section is concerned with specific analyses of the 150 reviewed doctoral dissertations. For comparative purposes, the data from the present review are portrayed and analyzed with the categories that are similar to those used by Gubi et al. [13] and Zachariassen and Arlbjørn [41]. The results are displayed in tables and are followed with appropriate comments and interpretations.

4.1 Number and type of dissertations finalized in the period 2009–2014

Table 1 contains the PhD dissertations divided by country, year of publication and type of dissertation (monograph vs. a collection of articles). Compared with the earlier studies, these new figures show some interesting developments. First, the number of finalized dissertations in the period 2009–2014 is 158, which represents an average of 26 dissertations per year. Compared with averages numbers of 10 (from the period 2002–2008) and 6.25 (from the period 1990–2001), this shows that there has been a strong increase in PhD production in this research area. A similar pattern is identified by Nakhata et al. [25] in their study of doctoral dissertations published by Dissertation Abstracts International in the period of 2005 and 2009. They explain that one reason for such an increase might be an increased level of retiring academicians toward 2020 which creates a stronger market for Assistant Professors. Another explanation could be that there is a drive from the governments to boost the number of annual PhD production in order to support national social, economic and environmental well-being as well as to address major global challenges [12]. The majority of the Nordic logistics and SCM PhDs come from the Finnish, Norwegian and Swedish research environments. In Denmark, the production is stable with 17 dissertations in the period of 2009–2014. Iceland has reported their first PhD in this period of analysis. Twenty-five Nordic research institutions have produced within logistics and SCM in the period 2009–2014 (see “Appendix 2”).

Another interesting finding in the current review is the increase in the share of dissertations that are based on a collection of articles. As given in Table 1, 92 out of the 150 dissertations (61 %) are based on a collection of articles. Thus, there is a much higher focus on the craft to write academic articles when compared to the share of article-based dissertations in previous periods (29 % in the period 2002–2008 and 21 % in the period 1990–2001). This trend supports the predictions previously made by Zachariassen and Arlbjørn [41]. One plausible explanation for this development might be an increased amount of public and private resource allocation to research environments based on publications in internationally recognized peer-reviewed journals as well as measures such as impact indicators and H-index (see, e.g., [27]).

4.2 Primary entity of analysis

In Table 2, all 150 dissertations are classified according to their entity of analysis; the classifications are also compared to previous results reported in [13, 14]. The study of the primary entity of analysis in the dissertations shows strong differences. First, the category others has increased to about one-third of the dissertations in the last reported period. This group consists of a variety of dissertations without a specific supply chain actors’ perspective—such as fresh fish supply chains [26] and healthcare logistics [17]. Second, in absolute numbers, the manufacturer as the primary entity of analysis has increased when compared to the previous studies; but, if we measure the number as a percentage of the reviewed dissertations, there is a fall from 57 % in the dissertations from 2002 to 2008 to 33 % in the recent study.

Thus, it shows the more classical actors such as wholesalers, retailers and inventory hotels have obtained lesser research focus. Additionally, a remarkably low number of dissertations have focused on retail SCM within the Nordic countries. This is intriguing given the fact that the retail sector is well known for supply chain innovations such as quick response systems, efficient consumer response, distribution centers, reverse logistics, as well as collaborative planning, forecasting and replenishment [10].

4.3 Level of analysis arranged according to year of publication

Table 3 shows the analysis of the dissertations level of analysis arranged by the year of publication.

An interesting development evidenced in the above table is an increased focus on functional themes within dissertations (in the present analysis, this is about 26 % of the dissertations compared with 11 and 10 % in previous analyses). This development is primarily driven by Finnish

Comparable data are included from the period 1990–2001 (Gubi et al. [13]) and 2002–2008 (Zachariassen and Arlbjørn [41])

dissertations and can indicate an emphasis on building stronger knowledge bases in certain sub-disciplines along the supply chain. Examples of such dissertations are [18, 19]. Another interesting development is the reduced focus on firm-level analysis and a subsequent increased focus on the supply chain or the network as the level of analysis, with the network level experiencing the highest increase. This increase is strongly evident within Swedish dissertations.

4.4 Research design, time frame and philosophy of science

Table 4 shows the classification of the dissertations according to research design, time frame and philosophy of

science. The recent analysis reveals a decrease in share of dissertations that are purely theoretical in nature. Also, the share of dissertations founded on purely qualitative methods has also decreased compared with dissertations published in the period 2002–2008. The drop in share of these two categories has attributed to increases in shares of dissertations based on quantitative methods and on triangulations of qualitative and quantitative research methods. The increase in quantitative research methods can be explained by the increased pressure to publish, thereby favoring quantitative methods over time-consuming qualitative studies (see, e.g., [21]). While quantitative data collection can be automated, it is not possible for qualitative data collection. Qualitative data collection is, in general, more time-consuming and expensive when compared

to quantitative research studies. Thus, it might be more cost-effective to slice one questionnaire survey into a number of articles than doing the same number of articles based on qualitative methodologies. This trend will

undoubtedly improve numerical performance metrics. At the same time, this trend need not necessarily deliver new knowledge that could move the discipline significantly forward. Particularly, quantitative surveys are exposed to

the phenomenon of “salami-slicing” where the data from a particular project are disseminated in a number of articles that in fact are “sliced” so thinly that there might be overlap of the papers (e.g., text recycling in literature review sections, key findings and discussions ([9, 16])). We refer to the Committee on Publication Ethics (COPE) [7] for a discussion on different forms of text recycling.

Table 4 also shows an increased share of dissertations that apply a longitudinal perspective. Additionally, the share of snapshot time frames has decreased and the share of the category time frame not specified has increased. Examples of dissertations without any specific time frame are by (1) Mortensen [23], who investigate the concept of attraction and explain its role in initiation and development of buyer–seller relations, and (2) Tynjälä [35], who conceptually examines the methods and tools for supply chain decision making during new product development. A final remarkable finding from Table 4 is the continued decline of dissertations containing philosophy of science issues. The present analysis identifies 73 % of the dissertations not including such philosophical considerations in comparison with 71 and 45 % in the two previous periods of analysis. Twenty-nine percent of dissertations that are monographs do contain philosophy of science considerations, whereas 25 % have this content among the article-based dissertations. Zachariassen and Arlbjørn [41] provided four possible reasons for this decline: (1) There are no mandatory requirements for PhD students to attend philosophy of science courses, (2) article-based dissertations do not rely on philosophy of science argumentations to the same degree as the monographs that typically require

more in-depth interaction of this issues and method considerations, (3) there is a lower prioritization of philosophy of science due to higher pressure from external funded projects that do not demand this theme, and (4) logistics and SCM are closely connected with industry that could lead to a perception that philosophy of science is less relevant. To this list, we add four more potential reasons. First, there are no requirements mentioned in Nordic countries’ ministerial orders granting degrees of PhD about unfolding philosophical of science perspectives. Second, few, if any, journals within logistics and SCM demand such discussions. Third, philosophy of science has disappeared from PhD candidates’ syllabi. Finally, only a few PhD advisors have the knowledge to join in such discussions with their PhD students; therefore, they do not send signals for offering such courses. Overall, this development is inexpedient if the discipline really has to move toward theory development [6, 30].

4.5 Dissertations distributed according to topic groups and country of origin

Table 5 displays the dissertations according to topic groups based on a title analysis of the 158 identified dissertations. For comparison reasons, the topic groups identified in previous studies were used [13, 41] and further supplemented with two new groups risk management and humanitarian logistics. The table shows a continued decline in the share of dissertations related to system design/structure/effectiveness, organizational development/competencies and material handling. In contrast, topics related to system integration/integration enablers and

Table 5 Division of dissertations according to topic groups and country of origin

A = Time period of 1999–2001 covered in Gubi et al. [13]

B = Time period of 2002–2008 covered in Zachariassen and Arlbjørn [41]

C = Time period of 2009–2014 covered in this paper

transport/transport systems have obtained increased awareness. The increase in these topics is primarily based on Swedish and Norwegian dissertations.

Additionally, while the study by [41] found that topics related to humanitarian logistics and risk management were absent, the present review of dissertations has remedied this with dissertations on this topic from Finland and Sweden.

4.6 Article-based dissertations

The study reported in this paper reveals an increased amount of article-based dissertations. This development confirms the expectations raised by Zachariassen and Arlbjørn [41]. However, an article-based dissertation can be composed in different ways—e.g., with respect to requirements regarding the type of articles, number of articles, co-author permission and the author order position among the co-authors in an article. The ministerial orders granting the degree of PhDs in the different countries do not provide any guidance and requirements concerning the format of a PhD. This opens up for various interpretations of the required workload to earn the PhD degree. Therefore, the increase in more article-based dissertations requires that we study how the practice of these types of dissertations is unfolded in the Nordic countries. This section takes a closer look at the 92 article-based dissertations and develops a measure to differentiate the various types of dissertations. The subsequent subsection proposes a measure for article-based dissertation; this measure is subsequently used in analyzing the identified Nordic article-based dissertations.

4.6.1 Measure for dissertation score

In order to develop a measure for an average article-based dissertation, we first need to recognize the fact that a specific article that is part of the dissertation can take different forms. Hence, the first element in this proposal for a dissertation measure is to differentiate between the different types of contributions that are part of the article-based dissertation and then to allocate different scores for the different types. The present analysis distinguishes between five different types of articles with specific scores as follows:

1. Peer-reviewed journal articles, score: 1
2. Peer-reviewed articles in form of book chapters (e.g., in an anthology), score: 0.8
3. Peer-reviewed conference articles, score: 0.8
4. Working papers, score: 0.5
5. Non-published papers, score: 0.5

The differences in scores are used to reflect different perceptions of workload as well as quality requirements. Thus, a peer-reviewed journal article obtains the highest score of 1 point followed by book chapters and conferences papers with scores of 0.8, and working papers and non-published manuscripts of 0.5 points.

The next step in developing a dissertation score is to propose a measure that takes into account the number of authors as well as the order of the authors. Thus, a sole authored paper by a PhD candidate counts more than a co-authored paper. And, in the present measure, a first-order author position counts more than a lower author position. Table 6 proposes scores for authorship indicators

Table 6 Authorship factor calculation

Number of authors (NoA)		Author order position (AOP)		Authorship factor
NoA	Score	AOP	Score	
1	1	1	1	1
2	0.9	1	1	0.9
2	0.9	2	0.9	0.81
3	0.8	1	1	0.8
3	0.8	2	0.9	0.72
3	0.8	3	0.8	0.64
4	0.7	1	1	0.7
4	0.7	2	0.9	0.63
4	0.7	3	0.8	0.56
4	0.7	4	0.7	0.49
5	0.6	1	1	0.6
5	0.6	2	0.9	0.54
5	0.6	3	0.8	0.48
5	0.6	4	0.7	0.42
5	0.6	5	0.6	0.36

evaluating each of the articles that take into consideration various numbers of authors and author order positions.

Based on the above proposals of different types of articles and measures for different authorship indicators, we can now develop an overall dissertation score based on Formula 1:

Formula 1: overall dissertation score

$$S = \sum_{i=1}^n T_i * \text{Authorship factor}_i$$

where S = overall dissertation score, T = type of article and authorship factor = number of authors (NoA) * author order position (AOP).

The overall dissertation score is composed of multiplying the scores of the individual articles by the authorship factor. The basic idea is that the highest score per article of 1 point is reduced based on the lower the level of the perceived status of various channels (e.g., journal rankings; journal articles versus book chapters; conference articles versus journal articles/book chapters) and the number of co-authors as well as the author order the PhD student has for the given article. A conference paper that is included in an article-based dissertation, which have been through a double-blind review process (e.g., at a NOFOMA, LRN or a EurOMA conference), is valued 0.8 compared with an article that is published in a peer-reviewed journal. Thus, a conference article is considered as less mature when compared to an article that has been through perhaps several revisions in a journal before acceptance. However, we should avoid with the generalization of the different channels. The Danish Bibliometric Research Indicator, for example, value accepted conference articles as much as some journal papers, if they are accepted to be presented at some conferences (e.g., EURAM and AOM) [36]. Also, contributions to books are valued differently according to which publisher the work is published with [37].

The dissertation score is a measure for the PhD dissertation at hand—and thus, the status of it when it was judged and passed. Several article-based dissertations contain non-published papers, working papers and conference articles that find its way to peer-reviewed journals after the degree of PhD has been awarded and further workload is invested in those articles. Other articles of this nature never end in publications for various reasons. Thus, the status of the papers after the PhD evaluation is not included in the dissertation score presented in this article.

An article-based dissertation is evaluated not only on the enclosed articles, but also on the text (the frame) that bind the articles together. Also, herein there seems to be different practices—e.g., the scope and depths on positioning the thesis against extant research; the level and scope of

methodological and philosophy of science discussions (see, e.g., [3]); independent literature reviews as well as discussions on the “red line” between the included articles.

The overall purpose with the dissertation score is to propose a measure to be used for discussing the scope and content-type of a PhD dissertation. What is enough? And how much of a dissertation can be co-authored with others? Is one dissertation better than another because it includes articles that are published? It is our experience that there are differences in what is needed in an article-based dissertation both within a department at a research institution and between research institutions. The present dissertation score can help in discussing what is needed and also in developing department guidelines.

The proposed overall dissertation score formula is not without limitations. First, the division of types of articles and their scores is subjective. The peer-reviewed journal category, for example, can be further divided into different scores by following specific journal ranking lists. Second, the scores for various numbers of authors and their author order position in the proposed authorship factor calculation are also subjective and can be altered. The order of authors of a paper does not necessarily display the true workload of different authors. The order of authors can be organized using different principles such as a simple alphabetical listing, organized after seniority (experience); listing the person first who got the idea to the article as the first author; or listing PhD students first because they need the credit more than their senior co-authors. Third, the dissertation score does not include a time perspective (i.e., the length of the PhD program)—a higher score can be obtained over a 5-year period when compared to a 3-year period. Fourth, the dissertation score does not take into consideration the extent of thesis frame (the text accompanying the articles such as scoping, positioning, methods, philosophy of science, contribution and implications). Fifth, the score of author order position decreases based on the position; this may not reflect the actual work load. In summary, as with any measures in general, this overall dissertation score also has its own shortcomings and these are important to be considered to ensure the practical use of the score. However, in spite of the sometime magical status of numbers—we should remember that “numbers are just number” and that they can be used to jump start discussions on how to compose an article-based dissertation.

4.6.2 Dissertation scores

This section provides an analysis of the 92 article-based dissertations using the dissertation score developed in the above subsection. This number is divided among 12

JA journal article, BC book chapter, CP conference paper, WP working papers, NP non-published paper

Danish, 27 Finnish, 37 Swedish and 16 Norwegian dissertations. As given in Table 7, the dissertations vary in the number of included articles spanning from three to eight articles. The majority of the dissertations are composed of four to six articles. The average number of articles counts to 4.84. Table 7 also shows that the average dissertation score increases from 1.53 with three articles to 5.38 with eight articles. This is not surprising given the design of the formula.

Furthermore, Table 7 shows that including journal articles is a well-established practice among the reviewed dissertations. The share of journal articles counts 54 % among dissertations with four articles (71/132); 62 % among dissertations with five articles (80/130); and 69 % among dissertations with six articles (99/144). After journal papers, conference papers and non-published papers are the second most typical types that are included in article-

based dissertations. Finally, Table 7 shows that including reviewed books chapters is not that prevalent among the dissertations reviewed.

This review also shows that there are more PhD candidates at Chalmers University of Technology with highest number of contributions at 18 dissertations followed by Molde University College with 16 dissertations and Lund University with 11 dissertations (see Fig. 1). In all, the 92 article-based dissertations contain 446 articles divided into the five types discussed in Sect. 4.6.1. Out of this, 266 are peer-reviewed journal articles of which 68 are from Chalmers University of Technology; 39 are from Molde University College; and 39 are from Lappeenranta University of Technology. In total, 83 articles are included as conference papers; 64 are included as non-published papers; 27 are included as working papers; and only six articles take the form of book chapters.

Fig. 1 Average dissertation scores divided by research institution. *AU* Aalto University, *ASB/AU* Aarhus School of Business/Aarhus University, *CUT* Chalmers University of Technology, *HSE* Hanken School of Economics, *JIBS* Jönköping International Business School, *KI* Karolinska Institutet, *LiU* Linköping University, *LU* Lund University, *LUT* Lappeenranta University of Technology, *MUC* Molde University College, *SU* Stockholm University, *TSE* Turku School of Economics, *TUD* Technical University Denmark, *UO* University of Oulu, *UV* University of Vaasa, *USD* University of Southern Denmark

Figure 1 demonstrates a relatively high variety among the dissertations across the different research institutions with respect to the average institutional dissertations (ranging from 1.47, 2.47, 2.76, 2.96, 3.03, 3.12, 3.22, 3.25, 3.45, 3.83, 3.87, 3.93, 4.11, 4.22, 4.28, 5.02). Four of the six dissertations composed of three articles (see Table 7) are Danish dissertations from Aarhus School of Business/Aarhus University. In contrast, eight out of the 24 dissertations holding six articles are composed of 4–6 peer-reviewed journal articles. The dissertation score is here suggested as an instrument that can be used in discussions on what is required to earn the degree of PhD at the specific research institutions and, through benchmarks, facilitate alignment processes if needed. With the limitations in mind, a PhD student can discuss with her or his advisor(s) as of what type of articles are required; whether co-authored articles with advisors or other senior researchers or PhD students can be included; and how a PhD student documents her or his contribution in each article if they are co-authored. The dissertation score can also stimulate further discussions on what should be included in the binder of the dissertation—e.g., prioritizes theme to be discussed in the binder instead of adding another article.

4.7 Potential topics for inclusion in the dissertations

The review process of the 150 dissertations reveals that five research areas seem to be under-prioritized among Nordic scholars within logistics and SCM. The topics are as follows (not prioritized):

- (1) *Cloud technology* Although there is a focus on maximizing the effectiveness of shared resources [5],

the increased availability of high-capacity network, low-cost computers and storage devices as well as the widespread adoption of hardware virtualization, service-oriented architecture, and autonomic and utility computing have led to a growth in the use of cloud technology. In spite of its increased importance, it is distinct that this subject has not received more attention in the dissertations reviewed.

- (2) *Globalization of SC* As mentioned previously, this topic was still largely ignored in the dissertation reviewed. With the natural outcome of expanding growing market and sustaining competitive advantage, companies have to make key decisions about managing costs and complexity through globalized supply chain (see, e.g., [11]).
- (3) *Supply chain innovation (SCI)* The discipline of innovations has branched out into the supply chain context and should be regarded as an important topic. While firms are applying their assets, operating resources and capabilities to develop new ways of improve performance, they cannot ignore the importance of their supply chain partners in enabling product and process innovations (see, e.g., [1]). Accordingly, more attention needs to be paid to this topic.
- (4) *Security* This topic was also mentioned in the previous study by Zachariassen and Arlbjørn [41]. Yet, this topic has only received limited attention among the 112 dissertations published between 2009 and 2014. Security is increasingly becoming a major concern to both private and public sector organizations. Security searches for cooperative arrangements between businesses as well as identifies risks

before the goods move. It is also concerned with controlling theft and reducing illegal import and export of stolen goods. There are many areas of research within the topic of security from formal aspects to empirical research (see, e.g., [4, 40]). Hence, it is essential that researchers start focusing on the different aspects of this topic in the future. This is one of the key topics of research within supply chain now as well as in the distant future.

- (5) *Big data* This is currently drowning the world. The huge amount of data is an invaluable asset in the context of supply chains. The quality of the evidence extracted significantly benefits from the availability of broad datasets. On the one hand, extensive vision is more promising when extra data are available. And, on the other hand, it is a big challenge. The current approach is not appropriate to handle large data, and therefore, there is a need for new solutions to handle large datasets. This research field is new and rapidly evolving [38], and there is also a lead-time issue before we see the first dissertations within this area. As a result, any initial effort taken will be a strong contribution from both experimental and theoretical perspective (see, e.g., [15]).

5 Conclusion

This paper has set out to analyze the development of Nordic doctoral dissertations in logistics and SCM from the years 2009–2014. The paper identified 158 dissertations relevant for review; out of this, 150 dissertations were reviewed in depth based on different criteria. Compared with previous studies, this research found several important developments in Nordic doctoral research. First, there has been an increase in the average annual number of finalized dissertations when compared to previous Nordic studies. The results predominantly show the remarkable increase in dissertations between 2009 and 2014 (158 dissertations) wherein Sweden ranks highest followed by Finland, Norway, Denmark and Iceland, respectively. Second, there has been a decrease in dissertations that focus on classical entities of analysis such as carriers, wholesalers, retailers and inventories. Therefore, it is clear that the PhD dissertation's focal point is still more on manufacturing firms (50/150) rather than on other entities. Third, there has been an increase in functional subject areas of logistics and SCM and the supply chain/network level. Fourth, the number of dissertations containing philosophy of science discussions is continuing to decline. As mentioned earlier, there is a significant increase in article-based dissertations and these dissertations do not adopt philosophy of science; as a

result, there is an extreme decrease (110/150). Finally, there is clear shift toward disseminating doctoral research as an article-based dissertation (2009–2014: 92/150; 2002–2008: 26/70; 1990–2001: 15/71, respectively). However, this piece of research has demonstrated that the content of the Nordic article-based dissertations varies along dimensions such as types of articles included, the number of articles included and the number of co-authors at the papers. A dissertation score has been suggested as a measure for initiating discussions about such dissertations at a single research institution and as a benchmark between different institutions. As discussed earlier, such a score is not without limitations and must not stand alone. Therefore, the next logical step might be to discuss how far should we go with the number and the type of contributions. What is enough in order to earn a PhD degree? The content of this paper can be used to match the expectations of PhD students and their supervisors so as to find the right path to learn the craft of conducting and disseminating logistics and SCM research.
